KERNEL ADDITIVE MODELING FOR INTERFERENCE REDUCTION IN MULTI-CHANNEL MUSIC RECORDINGS

Thomas Prätzlich, Rachel M. Bittner, Antoine Liutkus, and Meinard Müller

Abstract

It is difficult to acoustically shield microphones when recording a live music performance. In practice, each microphone also contains interferences from the other voices. In this paper, we aim to reduce these interferences in multi-channel recordings to recover only the isolated voices. Following the recently proposed Kernel Additive Modeling framework, we present a method that iteratively estimates both the power spectral density of each voice and the corresponding strength in each microphone signal. With this information, we build an optimal Wiener filter, strongly reducing interferences. The trade-off between distortion and separation can be controlled by the user through the number of iterations of the algorithm. Furthermore, we present a computationally effective approximation of the iterative procedure. Listening tests demonstrate the effectiveness of the method.

Goal 1: Interference Reduction

Example task: Remove interferences from strings and flute in the singer’s microphone channel

Goal 2: Learning of Interference Matrix

Learn contribution of each voice into each channel with Non-Negative Matrix Factorization (NMF)
Kernel Additive Modeling for Interference Reduction in Multi-Channel Music Recordings

Thomas Prätzlich, Rachel M. Bittner, Antoine Liutkus, and Meinard Müller

Algorithm

1. Input:
   - STFT for each channel $i$
   - Assignment of each voice $j$ to a set of channels according to $\phi$
   - Minimal interference $\rho$
   - Optional: A kernel for each voice

2. Initialization
   - For each frequency, initialize interference matrix with voice channel assignment and minimal interference $\rho$
   - Set initial estimate of voice’s images to STFT of associated microphone signal

3. Parameter Fitting
   - For each voice: Update the Power Spectral Densities (PSD) according to frequency dependent interference matrix
   - Optional: Apply a voice specific kernel median filter on each PSD that captures characteristics of each voice
   - Update interference matrix with NMF
   - Rescale each PSD and normalize

4. Separation Step / Output: Update the voice’s images

$$\hat{Y}_{ij}(\omega, t) = \frac{\lambda_{ij}(\omega) P_j(\omega, t)}{\sum_{j'=1}^{J} \lambda_{ij'}(\omega) P_{j'}(\omega, t)} X_i(\omega, t) \triangleq W_{ij}(\omega, t) X_i(\omega, t)$$

5. Iteration: For another iteration, return to step (3)

References

Evaluation – Listening Test

- Overall Quality
- Interference Reduction

Cello microphone
- Use information from the whole cello section
- More microphones are beneficial for interference reduction

Singer 1
- 1 microphone
- More iterations may decrease the overall quality
